

Part A

My individual contribution to this project was the integration of the map's UI and data scheme and general direction of the project in terms of scope and function. These contributions built on some of the skills I had, but mostly had me working outside of my comfort areas. I integrated the map UI with the rest of the project by utilizing [Leaflet.js](#) to cleanly showcase reports on our website and making sure our data format was in accordance with the other systems in our projects, namely the organizations and AI image classifier.

I learned a ton about frontend technologies, including React and Ionic, and how the web is a difficult yet rewarding space to work in. A success I had was in quickly learning how CSS can be used to make webpages look interesting and clean, and an obstacle was trying to learn React and Ionic before I even knew Javascript.

Part B

Our group accomplished creating a full stack application for crowdsourced litter reporting and pickup. The team was successful in delivering individual components, but we lacked agency in having regular meetings and hitting previously set milestones. We were however able to deliver a fully functional project, ready to be demoed by the day of the CEAS Expo.

My efforts were not as robust compared to theirs, especially with regards to creating working React code due to my inexperience with the framework and web technologies. A team member deserving of special recognition is Zach R., who was instrumental in creating our Supabase database layout and much of the React code that powered our application.
