

Our groups project was a Crowdsourcing Litter Application. It consisted of an Ionic React frontend, Supabase backend, and a Python AI classifier model. Individually, I contributed mostly to the database and backend. I created the tables in the database and added functions and row level security to help with operations on the backend. On the backend, I linked the database to the frontend with the built-in Supabase library found in React. I also made sure the frontend could successfully select, insert and filter the database as well as making sure authentication worked properly. I also contributed to every assignment throughout the semester. I did build on the skills identified in the initial assessment last fall. I built my Supabase and database skills in general and learned more about front end design. I improved these skills mostly through reading documentation and watching tutorials by others to learn best practices and other cool design tips.

Some things I learned about this semester include as mentioned above Supabase and Ionic React which are skills I built on but also Python ML classifier and models with PyTorch, and our Map API. I learned about PyTorch and our Map API by watching and talking with my group mates about what they were doing and how they were doing it. My success this semester was completing the backend and database. My obstacles included learning React, which was a framework that I didn't have a whole lot of experience with and figuring out how to implement our classifier with the rest of the system.
